Moving Charges and Magnetism

- Biot Savart law: The magnitude of Magnetic Field $d\overset{\longrightarrow}{B}$ is proportional to the steady current I due to an element $d\overset{\longrightarrow}{l}$ at a point P and inversely proportional to the distance r from the current element is, $d\overset{\longrightarrow}{B}=\frac{\mu_0}{4\pi}I\frac{d\overset{\longrightarrow}{l}\times\overset{\longrightarrow}{r}}{r^3}$
- Magnetic field due to long straight current carrying conductor:

$$B = rac{\mu_o I}{4\pi a} \left[\sin \phi_1 + \sin \phi_2
ight]$$

- ullet If conductor is infinitely long, $B=rac{\mu_o I}{2\pi a}$
- Right-hand rule is used to find the direction of magnetic field due to straight current carrying conductor.
- Force on a Straight Conductor: Force F on a straight conductor of length l and carrying a steady current I placed in a uniform external magnetic field B, $\overrightarrow{F} = I(\overrightarrow{l} \times \overrightarrow{B})$
- Lorentz Force: Force on a charge q moving with velocity v in the presence of magnetic and electric fields B and E. $\overrightarrow{F}=q(\overrightarrow{v}\times\overrightarrow{B}+\overrightarrow{E})$
- Magnetic Force: The magnetic force $\overrightarrow{F_B}=q(\overrightarrow{v}\times\overrightarrow{B})$ is normal to \overrightarrow{V} and work done by it, is zero.
- **Cyclotron:** A charge q executes a circular orbit in a plane normal with frequency called the cyclotron frequency given by $v_c = \frac{qB}{2\pi m}$ This cyclotron frequency is independent of the particle's speed and radius.
- Magnetic Field due to Circular current carrying Coil: Magnetic field due to circular coil of radius 'a' carrying a current I at an axial distance r from the centre-

$$B=rac{\mu_0 I a^2}{2(r^2+a^2)^{3/2}}$$

At the centre of the coil, $B=rac{\mu_0 I}{2a}$

• Ampere's Circuital Law: For an open surface S bounded by a loop C, then the Ampere's law states that $\oint\limits_C\overrightarrow{B}.\overrightarrow{d}\vec{l}=\mu_0I$ where I refers to the current passing

through S.

- ullet If B is directed along the tangent to every point on the perimeter, then $BL=\mu_0I_e$ Where Ie is the net current enclosed by the closed circuit.
- Magnetic Field: Magnetic field at a distance R from a long, straight wire carrying a current I is given by, $B=\frac{\mu_0 I}{2R}$

The field lines are circles concentric with the wire.

- Magnetic field B inside a long Solenoid carrying a current I: $B=\mu_0 nI$ Where n is the number of turns per unit length.
- For a toroid, $B=\frac{\mu_0 NI}{2\Pi r}$ Where N is the total numbers of turns and r is the average radius.
- Magnetic Moment of a Planar Loop: Magnetic moment m of a planar loop carrying a current I, having N closely wound turns, and an area A, is $\overrightarrow{m}=NI$ \overrightarrow{A}
- Direction of \overrightarrow{m} is given by the Right Hand Thumb Rule: Curl and palm of your right hand along the loop with the fingers pointing in the direction of the current, the thumb sticking out gives the direction of \overrightarrow{m}
- Loop placed in a Uniform Magnetic Field:
- 1. When this loop is placed in a uniform magnetic field B, Then, the force F on it is, F=0

And the torque on it is $\overrightarrow{ au} = \overrightarrow{m} X \overrightarrow{B}$

In a moving coil galvanometer, this torque is balanced by a counter torque due to a spring, yielding.

 $k\phi=NI$ AB Where ϕ is the equilibrium deflection and k is the torsion constant of the spring.

- Magnetic Moment in an Electron: An electron moving around the central nucleus has a magnetic moment μ_l , given by $\mu_l = \frac{e}{2m}l \text{ Where } l \text{ is the magnitude of the angular momentum of circulating electron about the central nucleus.}$
- Bohr Magneton: The smallest value of μ_l is called the Bohr magneton μBOr
